7. Tx Maximum E.R.P. Power Spectral Density

7.1. Block diagram of test setup

7.2. Limits

The Maximum e.r.p. power spectral density shall not be greater than the value allowed in annex B or any NRI for the chosen operational frequency band(s).

7.3. Test procedure

- (1) The test according to ETSI EN 300 220-1 V3.1.1 Clause 5.3.2.1.2.
- (2) Connect EUT's antenna output to spectrum analyzer by RF cable, the path loss was compensated to the results.
- (3) Set the spectrum analyzer as follows:

Centre Frequency:	The centre frequency of the channel under test
Span:	Wide enough to cover the complete power envelope of the signal of the EUT ($\geq$ Occupied Bandwidth).
Resolution BW:	100 kHz (see note).
Video BW:	100 kHz (see note).
Sweep time:	1 minute.
Detector:	RMS
Trace Mode:	Max Hold.
Note: In case the regulatory parameter is expressed in dBm/10 kHz, RBW & VBW should be set to 10 kHz.	

When the trace is complete, capture the trace, for example using the "View" option on the spectrum analyser.

Find the peak value of the trace and place the analyser marker on this peak. This level is recorded as the highest mean power (spectral power density) D in a 100 kHz band.

Alternatively, where a spectrum analyser is equipped with a facility to measure spectral power density, this facility may be used to display the spectral power density D in dBm/100 kHz.

Where the spectrum analyser bandwidth is non-Gaussian, a suitable correction factor shall be

determined and applied.

The maximum e.r.p. spectral density is calculated from the above measured power density (D and the applicable antenna assembly gain "G" in dB relative to an ideal half wave dipole, according to below formula. If more than one antenna assembly is intended for this power setting, the gain of the antenna assembly with the highest gain shall be used.

$$PD = D + G$$
